

Chapter -04 Using Python Libraries

1. Library:

A *Library* refers to a collection of *modules* that together *cater to specific type of needs or applications*. A *library* can have *multiple modules* in it.

Some commonly used Python Libraries are as listed below:

i) Python Standard Library:

This *library* is distributed with Python that contains *modules* for *various types of functionalities*. Some commonly used *modules* of Python standard *library* are:

- **math module**, which provides *mathematical function* to support *different types of calculations*.
- **Cmath module**, which provides *mathematical functions* for *complex numbers*.
- **Random module**, which provides *functions for generating pseudo-random numbers*.
- **Statistics modules**, which provides *mathematical statistics functions*.
- **Urllib module**, which provides *URL handling*, functions so that we can *access websites from within our program*.

ii) NumPy library:

This *library* provides some advance *math functionalities along with tools to create and manipulate numeric arrays*.

iii) SciPy library:

This is another useful *library* that offers *algorithmic and mathematical tools for scientific calculations*.

iv) tkinter library:

This *library* provides traditional *Python user interface toolkit* and help us to create user friendly *GUI interface* for *different types of applications*.

v) Malplotlib library: This *library* offers many *functions* and *tools* to produce *quality output* in variety of formats such as *plots, charts, graphs etc*.

2. Module:

A *act of partitioning* a program into *individual components (known as modules)* is called *modularity*. A *module* is a separate unit in itself. The justification for partitioning a program is that

- It reduces its *complexity to some degree*
- It creates a number of *well-defined, documented boundaries* within the *program*.

Or

A Python *module is a normal Python file (.py file)* containing *one or more* of the following objects related to a particular task:

- **docstrings** *triple quoted comments*; useful for *documentation* purpose. For *documentation*, the *docstrings* should be the first string stored inside a *module/function – body/class*
- **variables and constants:** *labels* for data
- **classes:** *templates / blueprint* to create *objects* of a *certain kind*.
- **objects:** *instances* of *classes*. In general, *objects* are representation of some *real or abstract* entity.
- **statements** *Instructions.*
- **functions** *name group* of instructions.

Hence, we can say that module '*ABC*' means it is a file '*ABC.py*'.

Note: Python comes loaded with some predefined *modules* that we can use and we can even *create our own modules*.

A module, in general:

- is independent grouping of *code* and *data* (*variables, definitions, statements and functions*)
- Can be *re-used* in other *programs*.
- Can *depend* on *other module*

3. Creating user defined Module:

The most common way to create a module is to define a *file* with the *.py* extension that will contain the code required to group separately from the rest of the application.

Example 1:

In this example we will create a *module* with *two simple functions* to display the *area and perimeter of rectangle*. We will then *import* and use these *functions* in *another file*.

Example module, namely Rectangle.py

```
#Rectangle.py

def Area_rec(s1,s2):
    area = s1*s2
    return area

def Perimeter_rec(s1,s2):
    peri=2*(s1+s2)
    return peri
```

Run the above code and type following on the **Python's shell prompt** >>> after importing the module with **import<module-name>** command:

```
>>> import <Rectangle>
```

After *importing* the module, module *Rectangle*, if we write;

```
>>> help(tempconversion)
```

Python will display all *docstrings* along with *module name, filename, functions' name and constants* as shown below:

```
>>> import Rectangle
>>> help(Rectangle)
Help on module Rectangle:

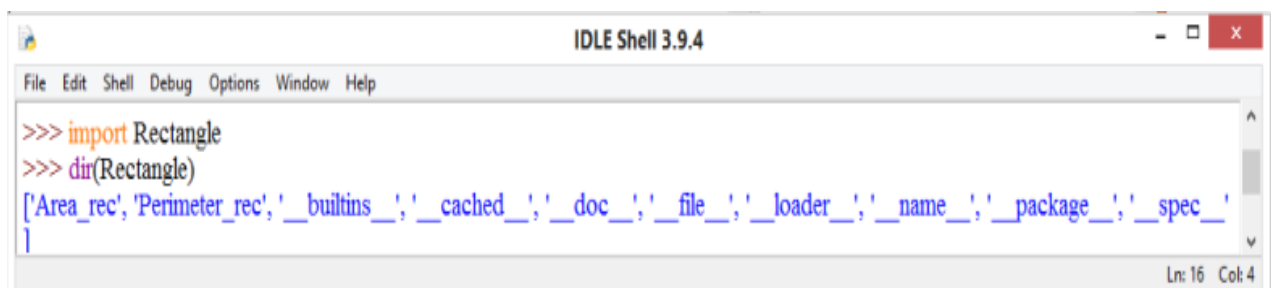

NAME
  Rectangle

FUNCTIONS
  Area_rec(s1, s2)

  Perimeter_rec(s1, s2)

FILE
  c:\users\naresh choudhary\appdata\local\programs\python\python39\assignments(2021-22)practical\class xia2 2021-22\chapter 4 using python libraries\rectangle.py
```

There is one more *function dir()* when applied to a *module*, gives us *names of all* that is *defined* inside the *module*

Example 2:

Example module, namely tempconversion.py

```
#tempconversion.py

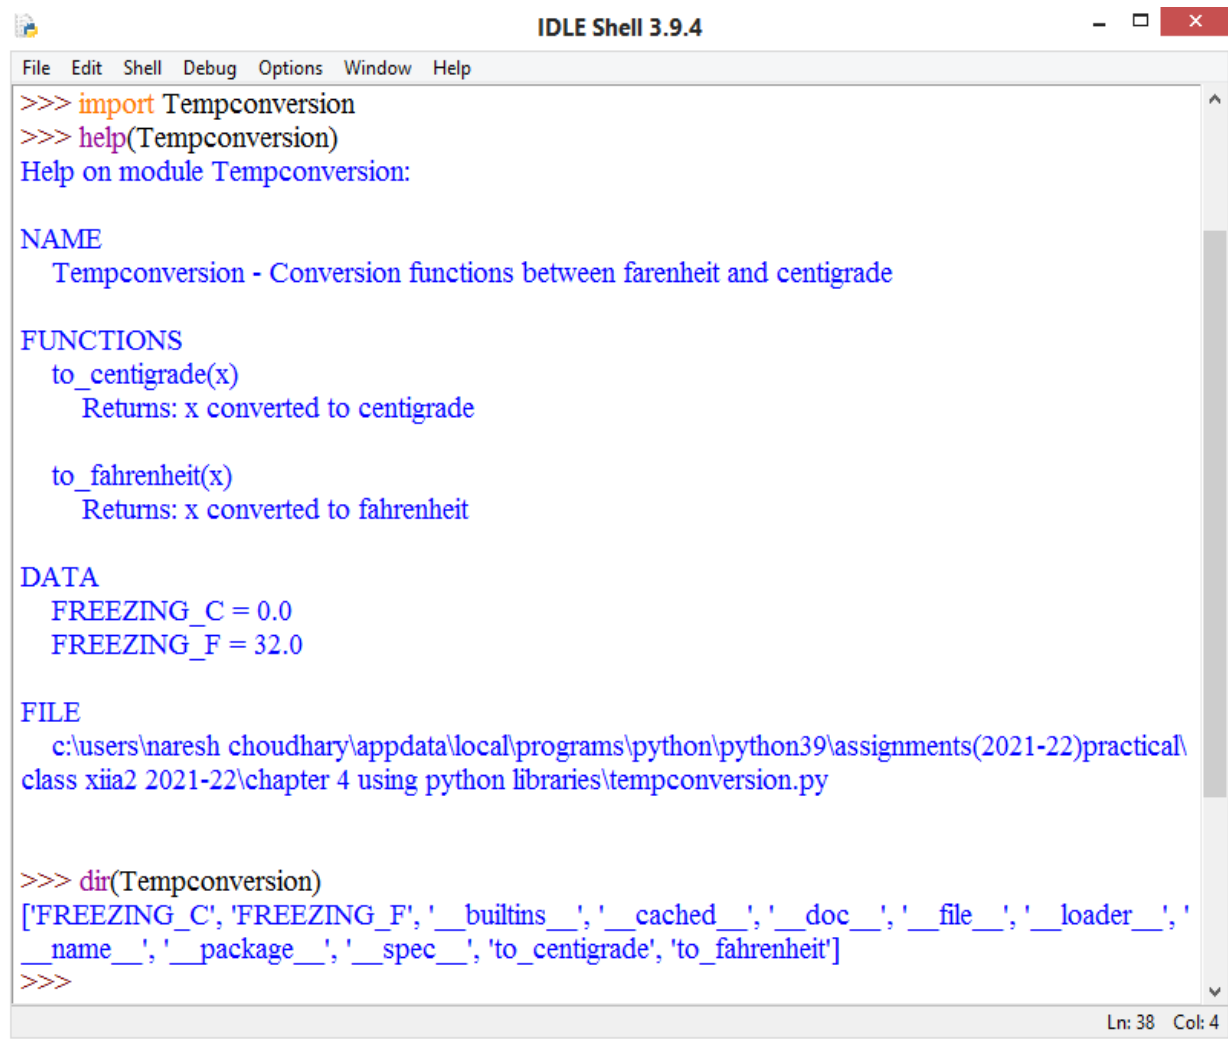

"""Conversion functions between fahrenheit and centigrade"""

def to_centigrade(x):
    """Returns: x converted to centigrade """
    return 5 * (x-32)/9.0

def to_fahrenheit(x):
    """Returns: x converted to fahrenheit"""
    return 9 * x /5.0 +32

#Constants
FREEZING_C = 0.0  #Water freezing temp. (in celcius
FREEZING_F= 32.0  #Water freezing temp. (in fahrenheit)
```

*Run the above code and type following on the **Python's shell prompt** >>> :*

```
IDLE Shell 3.9.4
File Edit Shell Debug Options Window Help
>>> import Tempconversion
>>> help(Tempconversion)
Help on module Tempconversion:

NAME
  Tempconversion - Conversion functions between fahrenheit and centigrade

FUNCTIONS
  to_centigrade(x)
    Returns: x converted to centigrade

  to_fahrenheit(x)
    Returns: x converted to fahrenheit

DATA
  FREEZING_C = 0.0
  FREEZING_F = 32.0

FILE
  c:\users\naresh choudhary\appdata\local\programs\python\python39\assignments(2021-22)practical\
  class xia2 2021-22\chapter 4 using python libraries\tempconversion.py

>>> dir(Tempconversion)
['FREEZING_C', 'FREEZING_F', '__builtins__', '__cached__', '__doc__', '__file__', '__loader__', '__name__', '__package__', '__spec__', 'to_centigrade', 'to_fahrenheit']
>>>
```
